## Simple probabilities in R

R has functions to compute probabilities based on most common distributions.

If X is a random variable with a known distribution, then R can typically compute values of the cumulative distribution function or:

$$F(x) = P[X \le x]$$

## Computing normal probabilities in R

To compute probabilities  $X \sim n(\mu, \sigma^2)$  is usually transformed, since we know that

$$Z:=\frac{X-\mu}{\sigma}\sim (0,1)$$

The probabilities can then be computed for either X or Z with the *pnorm* function in R.
